## Termite News

# Termites have more ways to enter your home than you do!

All you have is a front door, back door, and little or nothing beyond that. But termites don't need doors, or windows. All they need is the tiniest gap in concrete, mortar or metal, and they're in...hungry for wood.

If they don't immediately find the wood they want, these determined little engineers construct airtight, moisture-tight tubes leading from their colony in the soil to the wood. These tubes can go up walls, along pipes, around so-called "termite shields," and even stand free of any support. And the busy workers commute between their cellulose food and their colony. They collect moisture for themselves, and deliver nutrition to the members of the colony.

In this constant communicating lies their weakness. Prevent it, and you very quickly prevent further damage to your home. The only proven way of doing this is by placement of a chemical barrier, through which the worker termites cannot pass and survive.

By treating the soil around and beneath your home with a chemical effective against termites, you prevent this movement. The termites that are in your home return to the soil, and soon die. Those on the other side of the barrier cannot reach your home, so they seek other sources of food.

As professional Pest Control Operators, we have the knowledge, the experience, the materials and the equipment to protect your home against termite damage. Two typical techniques for applying termiticides are explained.

In the first technique, a trench is dug around the house's foundation. The termiticide is then applied to the soil in the trench.
